

ChatGPT for Learning: Grading Its Empathy and Inclusivity Across Identities

Jiayuan Liu from The PLAII Lab Adviosing Professor: Andrea Cuadra

Context

As Large Language Models (LLMs) like ChatGPT become common in classrooms, it's crucial to examine their performance as tutors, particularly in interacting with diverse student identities.

This poster explores a specific subtopic of this study, focusing on ChatGPT-4's display of empathy towards different gender identities in an online learning environment. The goal is to identify potential biases in ChatGPT-4 and compare its tutoring style with that of human teachers.

Questions Explored

- 1. "How does specifying the gender of a chatbot tutor impact ChatGPT's responses in conversation?"
- 2. "How does specifying a student's gender impact ChatGPT's responses in conversation?"

Method

- 1 Simulate online English teaching conversations using the TSCC corpus. At each teacher's turn, ChatGPT is prompted with the previous conversation and additional information about the gender or ID of the student or tutor to generate the tutor's response.
- 2 Use EPITOME Empathy Classifier to quantitatively evaluate the level of empathy displayed by the tutor in the simulated conversations.
- Identify patterns in simulated conversations through thematic analysis

Version 1: Only Gender ID Provided

- 6 Prompts
- ~20 conversations

increase authenticity

Version 2: Other aspects of ID Included

- 7 Prompts
- ~10 conversations

	Variable 1: Student	Variable 2: Tutor	Other
version 1	Options: a. Woman b. Man c. (non-specified) No other identity information provided	Options: a. Woman b. Man c. (non-specified) No other identity information provided	NA
version 2	Options: a. Woman b. Man c. (non-specified) With student's age, first language, certificate level provided	Options: a. Woman b. Man c. (non-specified) With student's age, first language, certificate level provided	No identity information provided

Findings

- Increased Empathy with Provided Gender Identity:
- ChatGPT displays more empathy when the student's and/or the tutor's gender identity is specified.
- Higher Emotional Response for "Woman" Identity:
- ChatGPT's Emotional Reaction (ER) score is significantly higher when the student's gender identity is "woman" rather than "man."
- No Significant Difference in Tutor Gender Empathy Scores:
- There is no significant difference in empathy scores between "woman" and "man" tutors.
 - Manual annotation reveals that "woman" tutors use more emotion-related words (e.g., "I'm excited to hear that...").
- Differences in Empathy Categories:
- ChatGPT's responses significantly differ from the original teacher's responses in all three categories of empathy.
- Impact of Additional Identity Aspects:
- When other aspects of the student's identity (age, first language, etc.) are provided, the difference in empathy scores caused by the student's gender is no longer significant.
 - The difference between "specified" and "not specified" identity aspects still exists.

Challenges

- 1. ChatGPT tends to generate longer messages that do not accurately reflect synchronous responses in conversation.
- 2. When analyzing the teacher's empathy score, response pairs in the initial conversation are not always adjacent.
- 3. Instances of repeated responses from ChatGPT.

Quantitative Result Example

Example graphs displaying three categories of empathy scores in version 1 for ChatGPT ("man student," "woman student," "non-specified student") and the teacher across 20 TSCC conversations. Based on T-test, the difference between "woman student" and "man student" is only significant in the ER type of empathy.

Comparing ChatGPT's scores in each category to the teacher's scores, it is evident that ChatGPT exhibits more emotional reactions and explores empathy more frequently but shows less capacity for interpretation. This likely occurs because ChatGPT can easily generate similar expressions of emotion and questions to check on the student but struggles to provide related stories and nuanced responses.

Conclusion

Providing ChatGPT with identity information impacts its responses, whether it pertains to the student's identity or the tutor role it is playing. However, the specific effects of different identity aspects or their intersectionality on ChatGPT's responses still require further investigation. This needs a more human-involved approach, as the empathy classifier cannot accurately assess the appropriateness of ChatGPT's displayed empathy. Additionally, important questions such as "When should LLM chatbots be given student identity information to improve teaching" and "how much of this identity should be disclosed" need to be further discussed in various contexts.
